

The folders involved in the server side of the webapp are the config, controllers, models, and routes folders. Config is where the instantiation of the app occurs, express starts the app and this folder also has a config.js which holds the keys to the database and key for the google maps later used to pinpoint a location of a building. Controllers are the ways the mongoose database can be manipulated this is most commonly done through queries. There is a controller for each one of the database schema. Models tend to relate the schema of a specified model to that of a database schema. Routes contains all specified routes that can be taken when it is called upon. This is where middleware is implemented making a coders life easier because less modification of code is needed and the methods included in middleware can exist indepently which leads to modularity of the code.
